## **AN UPDATE OF THE 1992 BENCHMARK INPUT-OUTPUT TABLE TO 1995**

Inforum has updated the 1992 benchmark I-O table for the United States to 1995. This update was done under contract to the Institute of International Trade and Investment (ITI). This report describes the data and reviews Inforum's approach to updating the table.

### *The Input-Output Table*

Detailed, "benchmark" I-O accounts are prepared about every five years by the Bureau of Economic Analysis (BEA) of the Department of Commerce. The benchmark tables are prepared for years in which comprehensive data from economic censuses is available. The benchmark table for 1992, which had 500 sectors, was published in November 1997. (See "benchmark Input-Output Accounts for the U.S. Economy, 1992", by Ann Lawson in the November 1997 Survey of Current Business.) BEA prepares both a "use" and a "make" table. The use table shows commodities purchased by each industry, and thus reflects the way in which census data was collected. The make table shows the commodities made by each industry. BEA also calculates a "commodity-to-commodity" table with the assumption of industry technology. With the industry technology assumption, it is assumed that the secondary products of an industry are made according to the input structure of that industry.

The Inforum I-O table differs from the BEA table in several respects. First, we derive an activity (or commodity-to-commodity) table with a process we call *purification*. A second consideration which Inforum has in regard to the I-O table is that it be reasonably up-to-date. We *update* the purified table. Our tables are not constructed from scratch; they are updates of the most recent (purified) benchmark table. Thus, an Inforum table remains as close as possible to the purified benchmark table while achieving consistency with all the data we can muster for the update year.

The Inforum table for 1995 is similar to the 1992 BEA table in terms of detail by sector. However, Inforum redefines some secondary products to primary activity to facilitate the derivation of a commodity table. (In the future, we hope to make splits in several sectors. Although separate sectors are shown in the SIC definitions, these splits have not yet been done. They include Crude Oil and Gas Extraction, Physicians and Dentists, and Fuel Oil and Petroleum refining.)

The Inforum updating technique produces a 1995 table with similar detail to the nearly

540 sectors in the purified 1992 table. We emphasize that these methods update a table, rather than construct one from scratch. With these methods, we identify various sources of output and final demands. A pre-balancing adjustment process insures that these estimates are consistent and reasonable. The final step is an iterative procedure which balances the table.

### *The Data Files*

The data files include Inforum's 1992 activity table (purfxd92.dat) and a 1995 activity table (a95r.dat). The activity tables are organized by producer. The files include only the non-zero flows. Data is valued in millions of dollars. The files include sector titles. The sectors are those available from the 1992 benchmark table, with the revisions described above. A title file (defn92.sic) includes the SIC classifications.

### **An Overview of the Inforum Approach**

The update process begins with the 1992 activity table which Inforum derived from BEA's 1992 Benchmark Use and Make tables. An activity table defines the columns (or purchasers) as commodities which match the definitions of the rows (or producers). A "use" table shows commodities sold to industries. The industry establishment definition includes, in addition to the products which are primary to the industry, secondary products. An activity table eliminates the analytical problems of the use table caused by secondary products. Inforum used its "purification" technique, which is described below, to derive its 1992 activity table.

After obtaining the 1992 activity table, the update process for a 1995 table begins. The update process included the derivation of row (or product output) controls and final demands by product. Next, an initial adjustment was made to the 1992 flows, to account for growth in current dollar output. Then the final demand flows, as well as the intermediate flows, were subject to an adjustment which insures that the subsequent iterative routine will not make unduly large changes to small intermediate flows. Finally, known final and intermediate flows were removed from the table, its row and columns controls were adjusted accordingly, and the remaining flows were balanced.

The rAs balancing technique is an iterative procedure in which the flows in each row, and then in each column, are scaled to match the row and column controls. After conflicts among different data sources have been resolved (which is a significant problem), convergence usually requires about ten iterations. These steps are described in detail below.

## Purification of the 1992 Benchmark Table

In dollar flow form, BEA publishes a "use" and a "make" table. A row of the use table shows the sales of a commodity to intermediate industries and to final demand. A column shows the purchases of commodities by an industry. A row of the make table shows the commodities produced by an industry. A column of the make table shows which industries produce a given commodity. This treatment conforms to the way in which data is reported to the Census Bureau. The reporting unit is an "establishment", which is classified as belonging to an industry on the basis of its primary product. The establishment reports all products which it makes. (This data helps build the make table.) It also reports materials purchased to manufacture its products. (This data helps build the use table.)

Although the use table is the most accurate way to tabulate Census data, a commodity-by-industry direct requirements matrix presents problems when used for input-output analysis. The presence of secondary products in the industry structure can lead to distortions in many types of analysis. These distortions may not be serious with a table of about eighty sectors, but with a table of 500 sectors (in which each manufacturing sector is a four-digit SIC product) the distortions can be quite bothersome. Therefore, it is desirable to derive a commodity-to-commodity table to eliminate the problems caused by secondary products. Two techniques are frequently employed: the industry technology approach and the commodity-technology approach.

The industry-technology approach assumes that the input structure associated with a given secondary product was the same as that of the industry making the secondary product. (This technique is recommended by the United Nations and was used by BEA to derive their 1992 commodity-by-commodity total requirements table.) It is simple to implement. But it implies that many different technologies are used to make a given product. Unfortunately, it can lead to unreasonable results. For example, do we want to assume that the cheese made as a secondary product of the ice cream industry has among its inputs such items as sugar, chocolate, and strawberries?

The commodity-technology approach is appealing for its economic sensibility. It assumes that secondary products are made with the input structure of the industry in which the product is primary. However, when reallocating materials from the industry in which the product is made, this method can yield negative flows. (It is for this reason that the industry-technology approach is often used.)

The Inforum "purification" technique starts with the commodity-technology assumption and provides a workable solution to avoid the problem of negative flows. This algorithm has been used in previous updates and was described in the report "An Update of the 1987 Benchmark Input-Output Table to 1990". It first postulates that each product is made by the same process, no matter what kind of establishment makes it. The vector of inputs into any establishment is therefore just a linear combination of the pure processes for the items it makes. An iterative algorithm (described in the 1990 report and in Appendix A of this report) solves for these pure processes. It avoids negative elements with a common-sense solution. When inputs associated with secondary products are transferred from the secondary to the primary sector, no more input is transferred than is available. Thus, an input can become zero, but it cannot become negative.

Although this algorithm works smoothly (it has been employed for the 1963, 1967, 1972, 1977, 1982, and 1987 tables), it does not produce a balanced table. The discrepancy could be resolved with a rAs balance, but this could lead to distortions in the I-O structure. Instead, we treat value-added as a residual. We also compare the residual value-added with the purified value-added. Where major differences occur, it is often possible to make sensible offsetting adjustment to the input structures of related products. As is often the case with input-output work, judgement needs to be added to mathematical techniques to obtain viable results.

## **Controls for the Update**

### *Product Output Control*

Output sources include the Annual Survey of Manufactures (ASM), Agriculture Statistics, the Minerals Yearbook, the Service Annual Survey, and the National Income and Product Accounts (NIPA). Most important among the sources are the series on five-digit SIC product shipments. These shipments, when adjusted for changes in inventories of finished goods, are the movers for manufacturing output. To derive the 1995 output levels, we multiply the 1992 BEA output by the index of growth shown in the Inforum output source.

Several types of NIPA data were utilized. NIPA series reflect data available from the annual revision of the NIPA that was released in August 1997. (See Parker and Seskin, "Annual Revision of the National Income and Product Accounts", Survey of Current Business, August 1997.) In addition, unpublished NIPA detail on consumer spending and non-residential investment was also consulted. BEA also provided its detailed estimates of Gross Output by

industry. Gross output is used by BEA to compile estimates of Gross Product by Industry (also referred to as value-added by industry). (See Lum and Yuska, "Gross Product by Industry, 1947-1996", Survey of Current Business, November 1997.)

### *Final Demands*

Detailed estimates, by product, of many categories of final demand were prepared for the 1995 I-O table. Such estimates were derived for personal consumption expenditures (PCE), producers' durable equipment (PDE), exports, imports, and inventory change. PCE and PDE for manufacturing rely primarily on the five-digit adjusted product shipments series. For non-manufacturing, the NIPA provide PCE estimates. Construction spending, by the private sector and by government, was derived from NIPA data. Merchandise exports and imports are taken from the Census Bureau trade publication Trade and Employment. Exports and imports of services are derived from BEA data in the Balance of Payments Accounts. For input-output work, estimates of inventory change by product are needed. However, most inventory data is available by holder. The Annual Survey of Manufactures (ASM) reports on finished goods, work-in-progress, and materials held in inventory. Estimates of manufacturing inventory change reflect the ASM data on finished goods and work-in-progress. For autos and trucks, inventory change was derived from the NIPA. Agricultural inventories are available from Agricultural Statistics.

For the government categories of final demand, we did not estimate demand by product. Instead, we estimated aggregate controls. The product structure was determined as part of the balancing for the intermediate, construction, and government matrices. The aggregate government controls were derived from Tables 3.7 (Government Consumption Expenditures and Gross Investment by Type), 3.17 (State and Local Government Current Expenditures and Gross Investment by Function), and 6.2 (Compensation of Employees by Industry) in the NIPA.

These sources provided estimates by which the 1992 value of final demand reported in the benchmark I-O table was moved forward to 1995. These initial estimates were then subject to a pre-balancing adjustment that is described below.

### *PCE and PDE*

A bit more explanation is in order for the PCE and PDE controls. From detailed I-O allocations, we have estimated the proportions of shipments that were purchased for personal

consumption and for investment in durable equipment, at the level of 5-digit SIC. Domestic product shipments are adjusted to include imports and exclude exports. The product of these ratios and the 1995 adjusted shipments yields an initial estimate for 1995 PCE and PDE for the manufacturing sectors.

We have relied on the five-digit detail for several reasons. Generally, at this level, it is possible to distinguish among consumer goods, PDE, and intermediate parts. The five-digit detail identifies military aircraft, for example. We rely on detailed product shipment data and these ratios to give us final demand estimates that are consistent with production data.

Of course, the National Income and Product Accounts (NIPA) also provide estimates of PCE and PDE. For several sectors, we rely on the NIPA for our primary estimates of PCE. All services, and within manufacturing, Gasoline, Fuel Oil, and Motor Vehicles, and Computers, are derived from NIPA data. However, for most manufacturing sectors, we rely primarily on the estimates derived from the five-digit shipment source. The major advantage of this data is its product-specific detail. Expenditure categories in the NIPA are often quite broad and cover many products. Data on retail sales is an important source of PCE for the NIPA, but retail establishments frequently sell a broad and changing array of products. Consequently, retail sales by type of establishment is often a poor indicator of purchases of specific products.

Experience has shown that the reconciliation of production data with PCE and PDE from the NIPA is not a simple task. Indeed, the preparation of an I-O table by BEA frequently results in significant benchmark revisions to the NIPA. Appendix B contains tables which compare estimates of PCE and PDE in the 1992 I-O table with estimates in the NIPA. Although aggregates are similar, there is often significant variation by category between the I-O and NIPA estimates. The NIPA do not yet reflect revisions based on the 1992 I-O accounts. Consequently, we have not controlled detailed PCE and PDE estimates to the NIPA. For manufacturing, we rely on shipments adjusted for foreign trade. From the NIPA estimates of PCE, we used estimates of services. We used total PCE and total PDE from the NIPA as an approximate guide for the totals in our updated table for 1995.

#### *Exports and Imports*

For the 1995 update, considerable effort was devoted to the reconciliation of source data for foreign trade with the 1992 I-O estimates. This reconciliation was made possible by access to the Transactions, Merchandise Export, and Merchandise Import workfiles. We thank the I-O Division at BEA for providing these workfiles to Inforum. The workfiles enabled us to relate

I-O allocations to Census and NIPA data. The 1995 estimates of exports and imports were derived from two sources. Merchandise trade was derived from "Trade and Employment" (TM95), a joint publication of the Census Bureau and the Bureau of Labor Statistics. Services were derived from the NIPA, supplemented with the Balance of Payments Accounts (BPA).

The Transactions Workfile showed the relation between trade in the I-O table and the categories of service exports and imports in the NIPA. For exports, the workfile was particularly helpful, because several NIPA service categories are represented in the I-O table as exports of manufactured goods. The NIPA categories for service exports include

- transfers under military agency sales contracts
- travel
- passenger fares
- other transportation
- royalties and license fees
- other private services
- other.

"Other transportation" includes port expenditures as well as the transport of freight. The BPA shows this detail separately, and also gives freight by mode of transport. The I-O workfile showed the 1992 composition of port expenditures (by mode), in terms of products identified by I-O sector. For example, the I-O workfile category, "ocean port expenditures in the U.S. by foreigners" appears in the I-O table as exports of Petroleum refining, Ship building and repair, Sawmill products, Water transportation, Communication services, Legal services, Insurance, Food, and other products.

Merchandise trade is based on the TM95 report, which published exports and imports by SIC. Unfortunately for future work, this report has been discontinued. In this source, exports were reported in "f.a.s." (free-alongside ship) valuation. We derived producers' values with the margin shares from BEA's basic 1992 I-O data file. In TM95, imports were reported in "c.i.f." (cost, insurance, freight) valuation. To derive domestic port prices, the I-O valuation, duties were estimated with the 1992 duty "margin", controlled to the NIPA aggregate.

However, to conform with I-O estimates, adjustments to Census merchandise trade are more complicated than these valuation adjustments. Here, the I-O export and import workfiles were invaluable. The export workfile identified, for detailed commodities, the following adjustments to Census merchandise exports:

- Canadian adjustment

- miscellaneous adjustment to non-Canadian goods
- military goods
- statistical difference
- BPA adjustment
- Puerto Rican adjustment.

The import workfile identified the following adjustments to the Custom's valuation of merchandise imports:

- ocean freight
- air freight
- land freight
- duty
- miscellaneous adjustment
- Puerto Rican
- re-exports.

For the 1995 I-O estimates, these adjustments were estimated with the 1992 proportions. For some of the adjustments (duties, re-exports, Puerto Rico), controls were available from the BPA.

The 1995 table defines non-comparable imports (NCI) in the same way that NCI were defined in the 1992 benchmark table. Domestically consumed imports of goods are all classified in the import column of final demand. (Earlier BEA tables treated some goods, such as bananas and coffee, as NCI. This treatment was changed with the 1992 table.)

### *Government*

The 1992 benchmark table, and the 1995 update, include new detail for final demand by government. This change conforms with changes in the NIPA introduced in the 1996 comprehensive revision. Gross investment is separated from current consumption expenditures by government. Current consumption expenditures include compensation of employees, purchases of goods and services, and a new item, the consumption of fixed capital. The "government industry" includes compensation of employees and consumption of fixed capital. Negative values in the government final demand columns represent negative "net purchases". That is, sales by government exceed purchases. For example, the negative entry in the State and Local Health column represents the sale of hospital services.

### *Intermediate Demand*

For the 1995 update, no controls were available for intermediate demand. The usual

source of such data is Census of Manufacturing. However, no economic censuses were conducted for 1995. (The economic censuses were conducted in 1992 and in 1997.) For the 1995 update, no census data was not available. Therefore, the initial estimate of intermediate flows was derived by assuming that the 1992 I-O coefficients were constant. These initial estimates then were revised by the update procedure.

## Balancing the 1995 Table

When all data estimates have been made, balancing proceeds in three steps: adjustment of 1992 intermediate and government flows for output growth or changes in final demand totals, a preliminary balancing adjustment to insure consistency between "known" final demand flows and output, and the iterative balancing by the rAs method.

### *Initial Estimate*

An initial estimate is made of the 1995 flows for which no independent information is known. The 1992 flows are updated with the growth in current dollar output of the purchasing sector. No independent data was available to update the intermediate flows.

### *A Pre-Balance Adjustment*

For each sector, the initial estimates are compared with product output. When many flows in a row are pre-determined flows, care must be taken to insure that such flows are consistent with output. Otherwise, unreasonable changes could be forced on the remaining small flows. Therefore, "known" intermediate and final demand flows are subjected to preliminary adjustment before starting the rAs process. This adjustment process was described in the 1990 report and in Appendix C of this report.

Prior to balancing, initial estimates for the update are adjusted. This adjustment insures that "known" flows are consistent with output. If known flows are large relative to other flows, the two kinds of flows receive almost the same adjustment. If they are small relative to other flows, the known flows will be relatively untouched by this preliminary adjustment. The adjusted

"known" flows are removed from row and column totals and the rAs balancing proceeds. It works much more smoothly after the preliminary adjustment than it does without it. This adjustment process is a key step in the update procedure. Because data is derived from many sources, our initial estimates may not be consistent with one another or with output. This technique helps reveal data inconsistencies. Appendix D shows the impact of this adjustment for each sector.

### *The rAs balance*

The rAs method completes the balancing process. Given a starting matrix, A, the method finds diagonal matrices  $r$  and  $s$  such that the matrix  $rAs$  has the required row and column sums, hence the name rAs. First, the adjusted "known" flows are subtracted from the corresponding row and column totals. In this iterative method, we first scale all the elements in each row to obtain the correct row sums, then scale all the elements in each column to obtain the correct column sum. The rows will then be out of balance, so we again scale them so that they have the right sums, then scale the columns again, and so on until the process converges. About ten iterations are necessary to get all the scaling factors to within one tenth of one percent of unity.

## **Acknowledgements**

The update of the I-O tables would not have been possible without the help of all of the Inforum staff. In particular, Amy Moxey Still and Farhat Mahmood helped update output data. Amy Still also maintained the data banks for the NIPA and Gross Product series. Funding from the Institute of International Trade and Investment in Tokyo, Japan, provided financial support for the project.

## Appendix A. The Purification Algorithm

Inforum derives an activity (commodity-to-commodity) table with a technique called "purification". This approach first postulates that each product is made by the same process, no matter what kind of establishment makes it. The vector of inputs into any establishment is therefore just a linear combination of the pure processes for the items it makes. In symbols:

$$f_i = Mp_i \quad (i = 1, \dots, n), \quad (1)$$

where:

$f_i$  (a column vector) is the transpose of the  $i$ th row of the primary flow matrix: that is  $f_{ij}$  equals the purchases of product  $i$  by the establishments in industry  $j$ .

$M$  is the product mix matrix:  $m_{ij} =$  the fraction of product  $j$  made in establishments in industry  $j$ . (The columns of  $M$  sum to 1.0.)

$p_i$  is the transpose of the row of the pure flow matrix:  $p_{ij} =$  inputs of product  $i$  into product  $j$ .

Equation (1) can be solved for  $p_i$  by

$$p_i = M^{-1}f_i \quad (i = 1, \dots, n). \quad (2)$$

The  $p_i$  vectors solved for by this formula will generally have some small negative elements and some small positive entries where the corresponding  $f_i$  vectors have zeros. The former are clearly nonsense; the latter are at best dubious and certainly inconvenient, especially as we move toward larger matrices for which we will wish to store only non-zero entries in our computers. By analyzing the solution of equation (2), we shall find a way to put a stop to this nonsense.

To simplify notation, let us drop the subscript i from f and p, and understand that the f and p in an equation all have the same i subscript. Equation (1) may then be written

$$0 = -Mp + f$$

and by adding p to both sides we obtain

$$p = (I - M)p + f. \quad (3)$$

The column sums of the absolute values of (I - M) will be less than 1.0, save in the unlikely case in which less than half of a product is produced by establishments primarily engaged in its production. The iterative process for the solution of (3) will therefore converge. In this process, we take as a first approximation of p,

$$p^{(0)} = f$$

and then define successive approximations by

$$p^{(k+1)} = (I-M)p^k + f. \quad (4)$$

To see the economic interpretation of equation (4), let us write out the equation for the use of a product, say steel, in making another product, say j:

$$p_j^{(k+1)} = f_j - \sum_{\substack{l=1 \\ l \neq j}}^n m_{jl} p_l^{(k)} + (1 - m_{jj}) p_j^{(k)}. \quad (5)$$

The first term on the right of equation (5) tells us to begin with steel purchases by the establishments of industry j. The second term directs us to remove the amounts of steel needed

for making the secondary products of those establishments, using our present estimates ( $p^{(k)}$ ) of the technology of those products. Finally, the last term causes us to add back the steel used in making product  $j$  in other industries.

The amount of steel added by the third term is exactly equal to the amount stolen, via second terms, from other industries on account of their production of product  $j$ :

$$(1 - m_{jj})p_j = \sum_{\substack{l=1 \\ l \neq j}}^n [m_{jl} p_l^{(k)}]$$

since  $\sum_{l=1}^n m_{lj} = 1$ .

It is now clear how to keep the negative elements out of  $p$ . When the "removal" term, the second on the right of equation (5), is larger than the "primary use" term, the  $f_j$ , we simply scale down all components of the removal term to leave a zero balance. Then instead of adding back the "total-stolen-from-other-industries" term  $(1 - m_{jj})p_j$  all at once, we added it back bit-by-bit, as it is captured. If a plundered industry runs out of steel with only a third of the total amount of plundering claims satisfied, we simply add only a third of each plundering products's claims into that products's cell in  $p$ .

Although this algorithm works smoothly (it has been employed for the 1963, 1967, 1972, 1977 and 1982 tables), it does not produce a balanced table. The discrepancy could be resolved with a rAs balance, but this could lead to distortions in the I-O structure. Instead, we treat value-added as a residual. We also compare the residual value-added with the purified value-added. Where major differences occur, it is often possible to make sensible offsetting adjustment to the input structures of related products. As is often the case with input-output work, judgement needs to be added to mathematical techniques to obtain viable results.

## **Appendix B. A Comparison of PCE and PDE in the 1992 I-O Table and the NIPA**

The 1992 I-O accounts were published in November 1997. The NIPA do not yet incorporate any of the results of the I-O study. The following tables compare I-O and NIPA estimates of personal consumption expenditures (PCE) and private investment spending for producers' durable equipment (PDE) in 1992. The NIPA estimates reflect data released in the August 1997 annual revision of the NIPA and are taken from unpublished BEA data that reported spending in million dollars and in additional detail that was not available in the published NIPA.

The first column of the table is Inforum's numerical designation of the spending category. The second column is the line number in the (unpublished) NIPA table for PCE or PDE. The third column is the NIPA estimate of 1992 spending. The fourth column is the I-O estimate. The fifth and sixth columns are the differences between the NIPA and I-O estimate, in dollars and as a percent. The last column is the title of the spending category.

Table B-1. Personal Consumption Expenditures

Table B-2. Private Investment Expenditures for Producers' Durable Equipment

## Appendix C. The Pre-Balance Adjustment

Prior to balancing, initial estimates for the update are adjusted. This adjustment insures that "known" flows are consistent with output. The pre-balancing adjustment is described below. If we let

- T be the row total
- K be the sum of "known" flows in the row
- S be the sum of the initial values of the other flows
- a = K/(K + S)

then we find z such that:

$$Sz + Kz^a = T.$$

We then adjust all the "known" flows by  $z^a$  and all the others by z. If K is large relative to S, the two kinds of flows receive almost the same adjustment; if K is small relative to S, the "known" flows will be relatively untouched by this preliminary adjustment. We then remove the adjusted "known" flows from row and column totals and proceed to the rAs balancing, which works much more smoothly after the preliminary adjustment than it does without it.

The preliminary adjustment is generalized to express different degrees of confidence in various groups of "known" flows. We then have

$$Sz + \sum_{i=1}^k K_i z^{a_i} = T$$

where k is the number of groups of "known" flows and the  $a_i$  expresses the degree of confidence in the flows in the  $i^{\text{th}}$  group. A value of  $a_i = 0$  means absolute confidence, while  $a_i = 1$  expresses minimal confidence. Our choice for a is convenient and, simultaneously, expresses approximately the confidence we feel in the estimate of the known flows.

This adjustment process is a key step in the update procedure. Because data is derived from many sources, our initial estimates may not be consistent with one another or with output. This technique helps reveal data inconsistencies. A table is included in the appendix which shows some examples which illustrate the need for a procedure such as this one.

## Appendix D. Data and Adjustments

The following table illustrates the pre-balancing adjustment procedure. Some Pre-Balancing Adjustments to 1995 Controls illustrates the adjustment made to each row prior to the rAs balance. This adjustment scales the entries in each row to conform with the row control. Large scaling factors often indicate problems with one or more of the data controls. The data shown in this table is our initial estimate. These initial estimates are often revised as a result of further data review or revisions in the estimation routines.

In this table, QBAL is the 1995 domestic output. CONTROL is the sum of output, adjusted for inventory change (ven), imports (imp), and "absolute precos". ABPTOT is the sum of the absolute precos (preconceived flows which are not subjected to the scaling in the pre-balance adjustment). PRECOS is the sum of preconceived flows and includes personal consumption expenditures (pce), gross private fixed investment (gpfi), and exports (exp). %PRECO is the ratio of precos to the control. NONPREC is the sum of other intermediate flows, nondefense (ndf) federal purchases, and state and local (slsum) purchases. "Z" is the adjustment made to the "nonprec" flows for which we had no control. "Z\*\*A" is the adjustment made to the "precos", the flows for which we had an initial data control. OVERALL is the average adjustment.
